Requirements example for ocean colour missions

- The 5% uncertainty was originally defined for satellite derived $L_{WN}(\lambda)$ in the blue spectral region to satisfy the 35% uncertainty in chlorophyll-*a* concentration determined for a specific bio-optical algorithm proposed for oligotrophic waters (Gordon and Clark 1981).
- This uncertainty assigned to satellite derived $L_{WN}(\lambda)$ prompts the need for uncertainties better than 5% for *in situ* $L_{WN}(\lambda)$ (still, in oligotrophic and likely mesotrophic open sea waters in the blue-green spectral regions). This requires *constraining individual sources of uncertainty of in situ radiometric data to within 1-2 % (commonly referred as 1% radiometry)*.

Above-water OC radiometry

Radiometric quantities

The basic quantity in radiometry is optical power (=radiant flux), measured in watts; $1 \text{ W} = 1 \text{ J/s}$.

"optical" in OC radiometry means $\approx (300..1000) \text{ nm}$.

Spectral representation: power is measured separately for each wavelength (hyperspectral radiometry).

Integral representation: power is integrated over certain wavelength range (multispectral radiometry).

Radiometric quantities: radiance and irradiance

Radiance $L(\varphi, \theta, \lambda)$: power, emitted from the unit area of the source into unit solid angle.

Unit: $\text{W} \cdot \text{m}^{-2} \text{sr}^{-1}$ or $\text{W} \cdot \text{m}^{-2} \text{sr}^{-1} \text{nm}^{-1}$

Irradiance $E(\lambda)$: total power, emitted from the unit area.

Unit: $\text{W} \cdot \text{m}^{-2}$ or $\text{W} \cdot \text{m}^{-2} \text{nm}^{-1}$

$$E(\lambda) = \iint L(\varphi, \theta, \lambda) d\varphi d\theta$$

$$\text{For hemisphere: } \Omega = \iint d\varphi d\theta = 2\pi \text{ sr}$$

Special case: Lambertian surface

Radiance $L(\varphi, \theta, \lambda)$ does not depend on the polar angles φ, θ :
the surface is perfectly diffuse (e.g. white snow, Sun's surface):

$$E(\lambda) = \iint L(\varphi, \theta, \lambda) d\varphi d\theta = \pi L(\lambda)$$

Diffuse (Lambertian) targets are widely used for calibration and characterization purposes.

Output data

RAMSES

Data acquisition and file conversion:
"MSDA_XE", records binary
(MS ACCESS) or ASCII datafiles.

All 256 pixel values are recorded,
pixel number 0..255 shown in datafiles.

Temperature data only available
for second generation (G2) devices.

HyperOCR

Data acquisition: "SatView",
records binary datafiles.

Binary-to-ASCII datafile conversion:
"SatCon".

Varying subrange of pixels is recorded
and converted.

Pixel number is not shown in datafiles.
Contains temperature data.

!!! Be careful when working with spectral data: pixel shift can easily happen !!!

Characterization and correction

Characterization is determination of the optoelectrical, mechanical and environmental properties of the radiometer.

Characterization takes mostly place in the laboratory by using dedicated light sources, environmental conditions and measurement procedures.

Characterization result: a correction factor or formula with uncertainty. This result belongs to the radiometer regardless of the measurement task.

The uncertainty of the characterization result depends on the capabilities of the radiometer and the characterization method.

The characterization result is used to correct any (laboratory or field) measurement carried out with the radiometer.

The characterized instrumental property will interact with the measurement conditions: the spectral and angular distribution and intensity of the radiation, temperature etc.

The magnitude and the residual uncertainty of the final correction depends on these conditions.

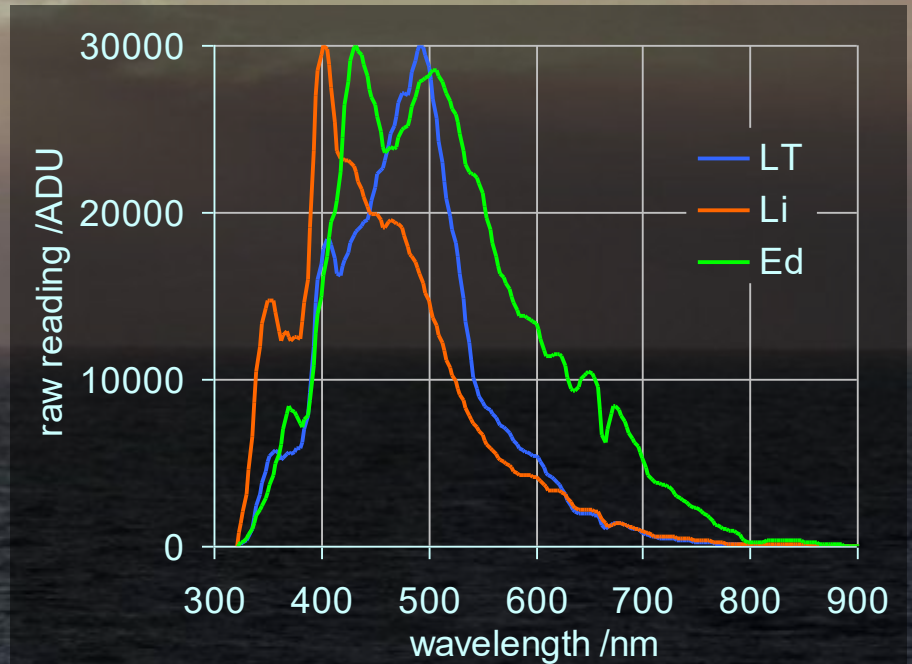

Test spectra and field conditions

The characterization results shown below belong to the real radiometers.

Due to the interaction between the characterization results and the field conditions, we need to define the example field spectra in order to evaluate the final corrections and residual uncertainties.

The example field conditions:

<i>SZA</i>	45 °
calibration temperature	20 °C
field temperature	30 °C
<i>DOLP</i>	0.4 (L_i)
	0.75 (L_T)
maximum raw signal	30000 ADU

Radiometric responsivity

Responsivity shows the ability of the radiometer to convert the input radiant power into output electrical/digital signal. Responsivity depends on the wavelength.

RAMSES

irradiance responsivity=output signal/irradiance

$$[1/(\text{mW} \cdot \text{m}^{-2} \text{nm}^{-1})]$$

radiance responsivity=output signal/radiance

$$[1/(\text{mW} \cdot \text{m}^{-2} \text{nm}^{-1} \text{sr}^{-1})]$$

HyperOCR

irradiance responsivity=irradiance/output signal

$$[\mu\text{W} \cdot \text{cm}^{-2} \text{nm}^{-1}]$$

radiance responsivity=irradiance/output signal

$$[\mu\text{W} \cdot \text{cm}^{-2} \text{nm}^{-1} \text{sr}^{-1}]$$

Radiometric non-linearity

Ideal case: output signal* of the radiometer is proportional to the excitation.
Reality: deviation from proportionality, usually at higher signal levels.

***Dark is subtracted**

Radiometric non-linearity examples

Measuring the radiometric non-linearity

For characterization of the radiometric non-linearity we need a signal source with **precisely controlled variable intensity**:

the varying distance method

Measuring the radiometric non-linearity

For characterization of the radiometric non-linearity we need a signal source with **precisely controlled variable intensity**:

Radiometric non-linearity

Output raw signal* of the radiometer is proportional to the integration time.
We can replace the varying excitation with varying output signal level by using different integration times.
The integration time ratios need to be precise.

*Dark is subtracted

Radiometric non-linearity

Empirical relationship, proposed by V.Vabson during the FRM4SOC Phase 1 project:

$$\frac{\Delta S}{S_{true}} = \frac{S - S_{true}}{S_{true}} = \alpha \cdot S_{true}$$

Valid for RAMSES and HyperOCR according to experimental results.

new graph

Radiometric non-linearity

The nonlinearity can be easily demonstrated when measuring a stable source with different integration times.

The non-linearity error for RAMSES and HyperOCR depends on the wavelength.

Derivation of the non-linearity coefficient

Calibration source is measured with two integration times $t1$ and $t2$:

$$\begin{cases} \frac{S(t1) - S_{true}}{S_{true}} = \alpha \cdot S_{true} \\ \frac{S(t2) - S_{true}}{S_{true}} = \alpha \cdot S_{true} \end{cases}$$

Will be solved for S_{true} and α ,
both depend on the wavelength.

The CP_*_RADCAL_* file

The CP_RADCAL* file contains $S(t1)$, $S(t2)$, lamp, panel etc. data, necessary for derivation of the cal factors and α with uncertainties. Calculation details can be found in HyperCP documentation.

The diagram illustrates the structure of the CALDATA file. It shows a table with columns labeled by arrows: pixel number, wavelength, cal factor, expanded uncertainty, $S(t1)$, and $S(t2)$. The table content is as follows:

pixel number	wavelength	cal factor	expanded uncertainty	$S(t1)$	$S(t2)$
[CALDATA]					
0	304.22	4	0.00	12	0.000000
1	307.55	0.299505	6.36	0.015587	0.022274
2	310.87	0.382907	4.82	0.015494	0.022285
...					
255	1143.49	0.000000	141.27	0.016136	0.023577
[END_OF_CALDATA]					

Comparison of the non-linearity measurement methods

The integration time method was compared to the more traditional beam addition method. The integration time method was modified by using monochromatic source. Non-linearity coefficient was determined at different sensor temperatures.

Radiometric non-linearity results

Individual characterization preferred because easy to perform during calibration.
Correction not recommended below 450 nm because of the noisy α .

Non-linearity correction of the field spectra

Each individual raw spectrum* can be corrected for radiometric non-linearity:

$$S_{lincorr} = \frac{-1 + \sqrt{1 + 4\alpha S_{meas}}}{2\alpha}$$

example case

*Dark is subtracted

Dark signal

Due to the constraints in optoelectronics and signal processing, the radiometer shows output signal even when the optical signal is blocked. The optical signal can be blocked with the internal (HyperOCR) or external (RAMSES) shutter.

Dark signal depends on the temperature and the integration time.

Dark signal shall be subtracted from the target signal before any further processing.

Dark signal originates from the light sensor and from the front-end electronics.

Dark signal shall be measured as close as possible to the target signal and with the equal integration time.

Dark signal is often handled by the acquisition or data conversion software.

Using of the stored or modelled dark signals is not recommended.

Dark signal can be used to derive the radiometer's internal temperature.

Dark signal examples

Dark spectra at 20 °C

RAMSES opaque pixels

Dark signal vs. temperature

Photodetector dominates the dark signal at longer integration times.
Temperature dependence of the photodiode is typically exponential.

At short integration times,
behaviour of the front-end
electronics becomes evident.

Front-end electronics: amplifiers,
ADC, voltage references etc.

Dark signal: detection of misbehaviour

Dark signal can be sometimes used to detect hardware problems.
No special equipment needed.
Immunity to the electromagnetic interferences can be examined.

perfectly random dark signal

dominating periodic component means noisy electronics or noisy environment

Uncertainty of R_{rs} due to the dark signal

During characterization we establish possible uncertainty of the applied dark level.
HyperOCR: thermal drifts between the target and dark acquisitions;
RAMSES differences between the modelled and real darks at higher temperatures and longer integration times (up to 50 ADU) + leak into the opaque pixels.
The uncertainty depends on the temperature, integration time and signal level.

high uncertainty due to the low raw signal levels of the natural targets

Signal-to-noise ratio (SNR)

Noise is random change of the output signal when measuring constant input.
Origin: fundamental processes in the underlying opto-electronical componets.
Noise magnitude depends on the signal level and temperature.

time domain

spectral domain

Signal-to-noise ratio (SNR)

raw signals

$$SNR = \frac{S_{light} - S_{dark}}{\sqrt{\sigma_{light}^2 + \sigma_{dark}^2}}$$

standard deviations

Be aware of temporal drifts when using standard deviation of the mean:

$$\sigma \rightarrow \frac{\sigma}{\sqrt{nf}}$$

nf : effective degrees of freedom, typically smaller than the number of averaged values.

standard deviation with autocorrelation

Drift of the time series shall not exceed 10% of the standard deviation. Otherwise, take autocorrelation into account.

Signal-to-noise ratio (SNR)

SNR 's correspond to the 30-fold averaging.

Uncertainty due to SNR

SNR of individual field signals*

Standard uncertainties due to the SNR *

*assuming averaging of 30 spectra

Wavelength scale

Use a spectral line source (discharge lamps, gas laser) to establish relationship between the wavelength and the pixel number.

Pen-Ray lamp
(Kr, Ar, Hg, ...)

low pressure
Hg lamp

Wavelength scale

Strong lines are detected first,
based on the tabulated spectral data.
The peaks are detected with
sub-pixel resolution.

A low-order polynomial is used
for approximation

Uncertainty due to the wavelength scale

The wavelength scale of RAMSES and HyperOCR was determined in the $+(5..40)^\circ\text{C}$ temperature range, uncertainties stay within $\pm 0.3\text{ nm}$.
Uncertainty of radiometric quantities depend on the slope of the spectra.

Example uncertainty due to the wavelength

SAMIP pixel 32 issue

The Inclination/Pressure module inside the RAMSES SAMIP devices occasionally interferes with the data communication.

Detection and correction algorithm available.

Pixel 31 has bogus signal

Rest of the pixel values are shifted by 1 position.

Spectral stray light

Ideal case: each pixel records signal at the pixel's wavelength.

Reality: certain amount of the pixel's signal is caused by other wavelengths.

Monochromator

Zeiss MMS1 module

Spectral stray light

For stray-light characterization, we use tunable monochromatic source to directly measure the line spread function (LSF) for each pixel. Tunable laser can be used instead of monochromator.

example LSFs

Spectral stray light

Line spread functions (LSF) are combined into stray light matrix (SLM).

LSFs in columns

$$\begin{bmatrix} z_{n0} & z_{n1} & \dots & 1 \\ \dots & \dots & \dots & \dots \\ z_{10} & 1 & \dots & z_{1n} \\ 1 & z_{01} & \dots & z_{0n} \end{bmatrix}$$

Spectral stray light

Spectral stray light re-distributes unwanted radiant flux between the sensor pixels. Accordingly, output signal is re-distributed to the wrong pixels. This process is mathematically called "convolution". In matrix formalism: multiply raw spectrum* by the *SLM*.

$$S_{meas}(\lambda) = SLM * S_{true} = \int SLM(\lambda - \Delta) S_{true}(\Lambda) d\Lambda$$

true signal (unknown)

distorted signal (measured output)

*Dark is subtracted

Stray light correction

Stray light matrix (SLM) can be used to correct individual raw spectra.

The correction is mathematically called "de-convolution".

De-convolution is an iterative process: search for the input spectrum S_{true} to give the measured spectrum S_{meas} after the convolution with SLM.

Two methods implemented in HyperCP:

de-convolution [Slaper 1995]

matrix method [Zong 2006]

Correction scheme:

Uncertainty due to the spectral stray light

Example uncertainty:

Thermal response

Expected temperature range during the field work is $+(2..40) ^\circ\text{C}$.

The instrumental parameters change with temperature.

Most significant are the changes in dark signal and responsivity.

Measure the dark close to the target signal and with the same integration time.

Responsivity change is caused by the detector, front-end electronics and thermal expansions of the opto-mechanical subsystem.

Responsivity change depends on the wavelength.

Measurement setup for thermal characterization

Thermal characterization is a lengthy process: relaxation times of ~ 1 h are required. This puts high demands on the temporal stability of the source and the alignment.

Thermal characterization method

Measure temporarily stable source at different radiometer temperatures to determine thermal coefficients of the radiometric responsivity.

Combine the experiment with characterization of the non-linearity, dark signal, wavelength scale, polarization sensitivity etc.

Thermal coefficients are evaluated separately for each pixel.

Measurement results are referenced to certain temperature, typically +20 °C.

Thermal coefficient
 $c_T(\lambda) = \tan \beta$

Correcting the field spectra:
 $S(\lambda, T_{ref}) = S(\lambda, T) [1 + (T - T_{ref}) c_T(\lambda)]$

raw or calibrated signal

Thermal response

Thermal characterization results are stored in the CP*_THERMAL_* files and processed by HyperCP.

family average $c_T(\lambda)$ and expanded uncertainty

individual $c_T(\lambda)$ and expanded uncertainty

Thermal response

Validation of the thermal characterization method: TO vs. JRC vs. Sea-Bird.

Fast temperature change:
temperature sensor signal does
not follow the responsivity.

Uncertainty will increase.

Dark signal is good temperature proxy.

Uncertainty due to the thermal response

Error caused by 10 °C difference between the calibration and field temperatures.

L_T , L_i and E_d radiometers belong to the same family.

Residual uncertainty after temperature correction

Angular response characterization setup

Angular response can depend on the azimuth plane. Zero azimuth is marked with a red dot on the radiometer's body.

Angular response

Lamp and lens form a collimated beam.

Incident angle is changed by rotating the radiometer.

Characterization result: normalized responsivity vs. incident angle for each pixel.

Angular response is currently measured in two perpendicular principal planes.

Results stored in the CP_*ANGULAR_* files and processed by HyperCP.

The corrections are currently not applied, but the uncertainty is evaluated.

Angular response examples: radiance sensors

FOV of the RAMSES and HyperOCR radiance sensors

FOV of the modified RAMSES sensor in two principal planes

Angular response examples: irradiance sensors

For uncertainty estimation we need direct-to-diffuse ratio of the downwelling irradiance. Uncertainty component for R_{rs} is close to the integral cosine error (which is close to the cosine error around 45° incident angle).

estimate for the uncertainty of E_d and R_{rs}

Polarization of light

Optical radiation is an electromagnetic wave.

Electromagnetic waves are transverse: the electric and magnetic vectors are perpendicular to the direction of wave propagation.

In the case of unpolarized light, all vector directions have equal probability.

Light detectors average the electric vector magnitude into electrical signal.

Polarization of light

Scattering and reflection change the radiation's degree of polarization.

Polarization sensitivity

Polarization state of the radiation is described by Stokes vector.

Interaction with the polarized light is described by the Mueller matrix.

[Kostkowski: Reliable spectroradiometry]

Characterization of radiometers: determine responsivity at different angles β .

[Talone 2016]

Diffuser of the irradiance sensors de-polarizes the input radiation.

Characterization of the radiance sensors is needed.

Measurement of the polarization sensitivity

Output radiation of the sphere is unpolarized. Polaroid is rotated around the optical axis and the radiometer's output signal recorded. Angle of the maximum responsivity is referenced to the "red dot".

Polarization sensitivity

Because the detector acts on the magnitude of the electric vector, responsivity shows two maxima and minima per full rotation of the polarization plane.

Polarization sensitivity depends on the wavelength.

Amplitude and phase angle of the signal change are reported in CP_*_POLAR_* files.

device-specific phase angle

Uncertainty due to the polarization sensitivity

Degree of linear polarization (DOLP) of the OC signals are needed to evaluate the uncertainty due to the polarization sensitivity of the radiance sensors.

[Mobley 2015, D'Alimonte 2016, Voss 2010]

Uncertainty of R_{rs} corresponds to the "worst case" scenario.

Uncertainty of R_{rs}

contributions if not
corrected

with and without corrections

Conclusions

The instrument characterization results cannot be directly converted into the uncertainty of the OC products as the measurement conditions and properties of the measurand affect the result.

Radiometric calibration, linearity angular and thermal sensitivity contribute the most.

The number and the motivation of the labs regarding the opto-electronical characterizations are insufficient

Cooperation with manufacturers to improve the instrument parameters

Develop a reference radiometer
